

Thermistors

NTC thermistors

The **RS** range of NTC thermistors includes standard tolerance negative temperature coefficient thermistors, a range of small close tolerance R/T curve matched thermistors and a range of DO-35 package devices.

Standard tolerance thermistors

A range of 13 negative temperature coefficient bead thermistors and 4 disc thermistors constructed from a compound of nickel manganite. Of the 13 bead thermistors, ten types are sealed in glass and three are incorporated into stainless steel probe assemblies. This range was designed primarily for temperature measurement and control, flow measurement and liquid level detection. The four NTC disc thermistors are intended for use in temperature compensation, measurement and control applications. Disc diameter in all cases is 10mm with a lead pitch of 5mm (nominal).

The range of DO-35 packaged NTC thermistors is designed for temperature measurement and control in applications which demand cost effective reliability. Typical applications include domestic appliances, automotive systems, data processing equipment and heating/ventilating/air conditioning control.

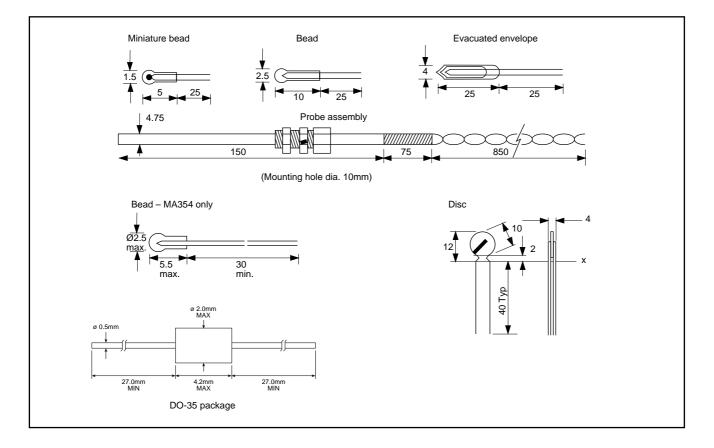

The hermetically-sealed construction combines the advantages of high temperature operation and high reliability of glass bead types with the closer tolerances associated with chip devices. The glass encapsulation offers the additional benefit of high voltage insulation.

Basic formulae

The temperature coefficient \propto at any temperature within the operating range may be obtained from the formula:

$$\infty = -\frac{B}{T^2} (\text{per }^\circ \text{C})$$

To determine the resistance at any temperature within the operating range may be obtained from the formula:

$$\begin{pmatrix} \frac{B}{t_2} - \frac{B}{t_1} \\ R_2 = R_1 \cdot e \end{pmatrix}$$

where:

- B = characteristic temperature constant (°K)
- T = bead temperature in (°K)
- R_1 = resistance of thermistor at temperature $t_1(\Omega)$
- \vec{R}_2 = resistance of thermistor at temperature $\vec{t}_2(\Omega)$

e = 2.7183

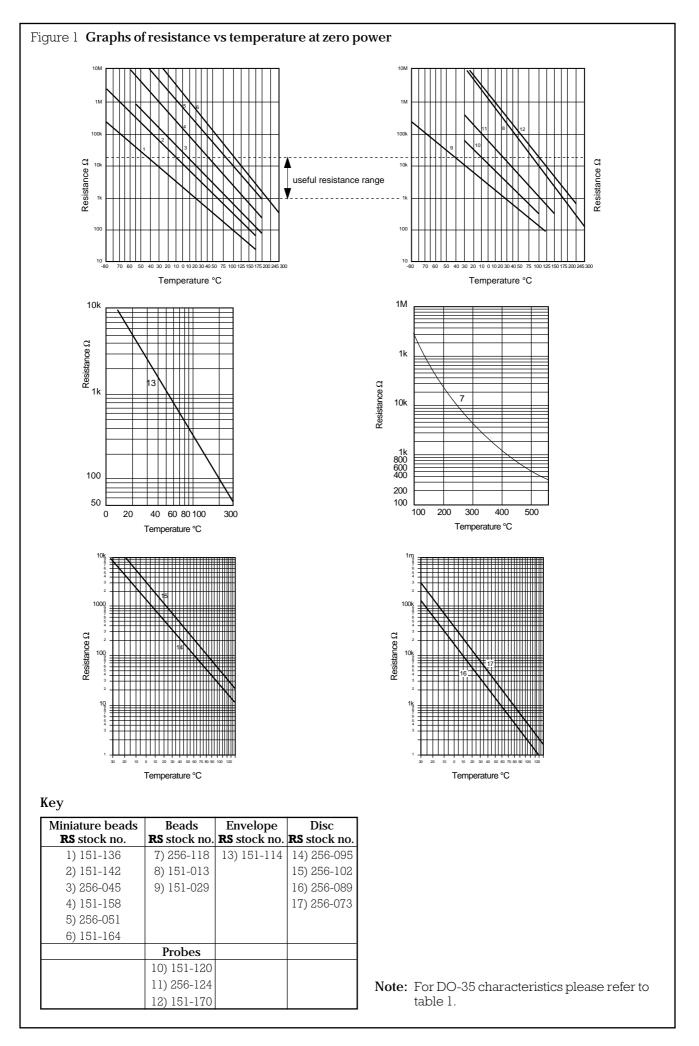

(Temperature in $^{\circ}$ K = temperature in $^{\circ}$ C +273).

Application notes

Typical applications include temperature control of ovens, deep freezers, rooms and for process control, etc. Can also be used to drive high and low temperature alarms.

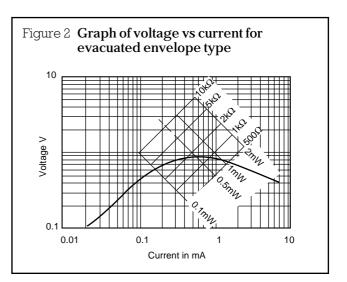

In the basic circuit below, calibration should be carried out by comparison with a known standard (eg. a thermometer or thermocouple). In the case of 0°C, a mixture of ice and water can be used and for +100°C, use boiling water.

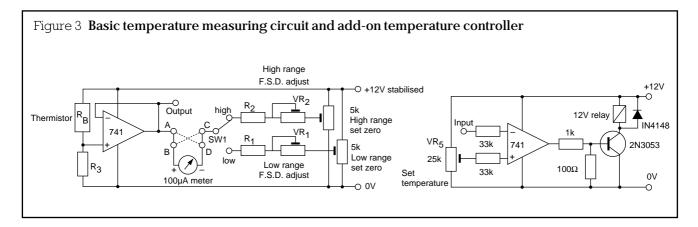

Note: that non-linearity should be expected at extended temperatures.

R-T curve matched thermistors

A range of high quality precision curve matched thermistors, available in four characteristic resistances. The range offers true interchangeability over a wide temperature range and eliminates the need for individual circuit adjustments or padding. These thermistors provide accurate and stable temperature sensing capability for applications such as temperature measurement and compensation.

| Dissipation constant | | lm | ιW | |
| Time constant | | 10 |)s | |

Definitions

Dissipation constant. Represents the amount of power required to raise the temperature of the thermistor 1°C above its ambient temperature, expressed in milliwatts.

Time constant. The time required for the thermistor dissipating zero power to change 63% of the difference between its initial temperature value and that of a new impressed temperature environment.

PTC thermistors

The RS range of PTC thermistors includes three types for over-temperature protection and four types for over-current protection.

Over-temperature protection

A range of three positive temperature coefficient (PTC) thermistors, manufactured from a compound of barium lead and strontium titanates. The range consists of two disc types and one stud mounted version. These devices are primarily designed for temperature sensing and protection of semiconductor devices, transformers and motors etc. As can be seen from the resistance/temperature characteristics of Figure 6, the resistance of the PTC thermistor is low and relatively constant at low temperatures. As the ambient temperature increases, the resistance rises. The rate of increase becomes very rapid at the reference temperature (Tr) of the device. Tr is also known as the threshold, critical or switching temperature. Above Tr the characteristic becomes very steep and attains a high resistance value.

| Specification | | Stud | Disc | | |
|---|-----|---------|--------------------|--|--|
| RS stock nos. | | 158-250 | 158-266 158-272 | | |
| Maximum operating and storage temperature | | 155°C | Tr + 100°C | | |
| Minimum operating and storage temperature | | –20°C | –55°C | | |
| Typical thermal resistance (embedded) | (l) | - | 0.05°C/mW | | |
| Typical dissipation constant (embedded) | (l) | - | 20mW/°C | | |
| Maximum power dissipation at 25°C | (2) | _ | 690mW | | |
| Maximum applied voltage at 25°C | (2) | - | 40V | | |
| Insulation between stud and lead | | 500Vdc | - | | |
| Typical resistance at or below Tr –20°C | | | 100Ω | | |
| Maximum resistance at or below Tr –20°C | | 1 | 250Ω | | |
| Maximum resistance at Tr –5°C | (3) | Ę | 550Ω | | |
| Typical resistance at Tr | (3) | 1000Ω | | | |
| Minimum resistance at Tr +5°C | (3) | 1330Ω | | | |
| Minimum resistance at Tr +15°C | (3) | 4 | 000Ω | | |

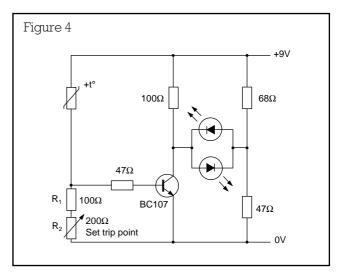

Notes:

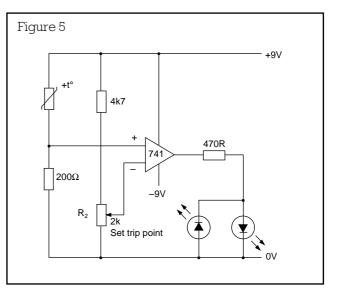

1. Dependent on method of insulation and mounting

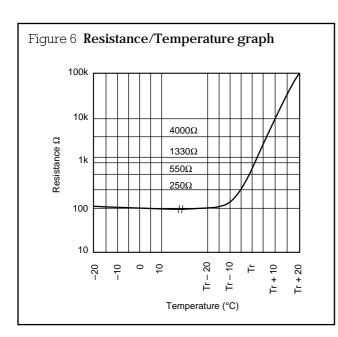

2. Self heating in free air

3. Measured at 2.5Vdc

4. Measured at 7.5Vdc.

Calibration

Calibration should be carried out by heating the thermistor to the appropriate reference temperature and adjust R_2 such that the appropriate LED lights.

Series connection

In temperature sensing circuits two or more devices may be connected in series. The sensing circuit will then indicate if any of the thermistors exceeds the reference temperature. An increase in the value of R_1 may be necessary to compensate for the additional voltage drop across the thermistor.

Application notes

Basic temperature sensing circuits.

Figure 4 shows a basic circuit which indicates when the temperature of the PTC thermistor is below Tr (ie. safe operation) and will also indicate when Tr is exceeded. When both LEDs are off this indicates the Tr is being approached (approx. Tr -5° C).

Figure 5 shows a circuit which has a more defined 'trip point' than Figure 4 (set by R_2).

Over-current protection

Switching type Positive Temperature Coefficient (PTC) thermistors are prepared from barium titanate to give a ceramic disc. Electrical contacts are made by the metallising of the disc faces using nickel, silver, etc; the completed disc is then provided with soldered lead wires.

Definition of terms

- $\begin{array}{rcl} R_{min} & & Resistance \mbox{ of PTC at lowest point of } \\ & R \, v \, T \, curve. \end{array}$
- $R_{_{25}} \qquad \quad \text{Resistance of PTC at } +25^\circ\text{C}.$
 - Not tripped temp. current.
 - Trip temp. current.
- $I_{\scriptscriptstyle rest} \qquad \quad Current \, value \, at \, V_{\scriptscriptstyle max}.$
 - Maximum allowable current through PTC.
- V_{max} Maximum voltage that may be applied to thermistor.

Theory of operation

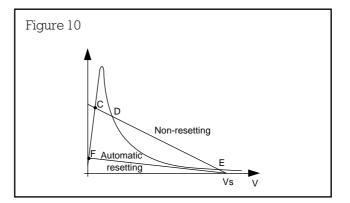

The shape of the PTC thermistor resistance vs temperature characteristics (Figure 8) can be considered in three distinct parts. The region from below 0°C to R_{min} has a negative temperature coefficient of the order of 1%/°C; the region from R_{min} to R_{max} has a positive temperature coefficient in which values as high as 100%/°C can be realised. Beyond R_{max} the TC is again negative. As a PTC thermistor is sensitive to voltage variation. R vs T curves are usually measured at a constant voltage. Figure 9 shows the characteristics of the load to be protected, together with the I/V of the thermistor on a linear scale. Region 'A' indicates the permissible load current range for normal operation.

An increase in load current beyond the $I_{\rm max}$ value will cause the thermistor to self-heat to a high resistance state thereby shifting its operating point to the region B. This reduces the current through and voltage across the load, effectively protecting the equipment, etc.

Similarly, if the ambient temperature surrounding the thermistor should, due to a fault condition, increase, the I/V curve will depress towards the dotted position. The load attempts to consume more than $I_{\rm max}~(+55\,^{\circ}{\rm C})$ and the thermistor will again self-heat and shift its operating point into the low current region.

Selection

In order to ensure that the load is protected at the desired level and in the required reset mode, the following parameters must be taken into account:

1. Normal operating current range – Region 'A'.

- 2. 'Overload' current Imax
- 3. Operating temperature range I/V curve shift.
- 4. Operating voltage range (Vs).
- 5. Time response position in Region 'A'.
- 6. Thermistor tolerances.
- 7. Permissible voltage drop across device.
- 8. Mounting arrangement.

The reset mode required, ie. return to the 'A' region, is decided by the position of the load line in relation to the I/V curve. Figure 10 shows load line positions for the two modes, the auto-reset line intersects the I/V curve at only one point (F), thereby restricting stable operating to this point for normal load conditions. The manual or non-resetting line crosses the I/V curve at three positions, giving the possibility of operation at either point. However, point D is in an unstable region so that in practice operation only occurs at points C or E.

If response time is a particularly important factor, the position of the operating point within region 'A', for a given device (Figure 9) and the switch temperature of the PTC must be carefully considered. In circumstances where the circuit being protected is subject to short term overloads (which may be tolerated), the operating point should be the lower portion of region 'A'. Alternatively, where response time must be rapid, the operating point must be as close to the $I_{\rm max}$ value as practicable, not forgetting the shift in characteristic with temperature.

Tolerances are usually quoted on the room temperature resistance (zero power), the higher values of $R_{\rm zs}$ giving the lower $I_{\rm max}$

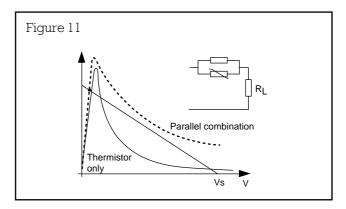

As a thermistor is a resistive device there will inevitably be a voltage drop across it when in circuit. The maximum permissible voltage drop for the circuit concerned will dictate the room temperature or R_{zs} resistance value. It is usual to make the R_{zs} value in the order of 10% of the circuit resistance (or impedance).

The thermistor should be positioned in the equipment such that the surrounding air is reasonably still and unconfined. Moving air will effectively increase the $I_{\rm max}$ value (at a given temperature) whilst confining the device will create a high ambient temperature, and therefore a lower $I_{\rm max}$

Modification of I/V characteristics

In certain applications it is necessary to modify the I/V curve in order to produce the necessary characteristics. To obtain an auto-resetting device with a relatively high current rating, a resistor may be connected in

parallel with the thermistor to 'lift' the characteristic to the dotted position (Figure 11). This permits the load line to occupy a position in the upper 'A' region, but still crossing the combination curve at one stable point.

Parallel operation

In instances where a sufficiently high $I_{\scriptscriptstyle max}$ value cannot be realised with existing devices, it is permissible to parallel connect two or more devices to achieve the required values; this may also be used to obtain lower $R_{\scriptscriptstyle xs}$ resistances.
