LM56
Dual Output Low Power Thermostat

General Description
The LM56 is a precision low power thermostat. Two stable temperature trip points \(V_{T1}\) and \(V_{T2}\) are generated by dividing down the LM56 1.250V bandgap voltage reference using 3 external resistors. The LM56 has two digital outputs. OUT1 goes LOW when the temperature exceeds \(T1\) and goes HIGH when the temperature goes below \((T1-THYST)\). Similarly, OUT2 goes LOW when the temperature exceeds \(T2\) and goes HIGH when the temperature goes below \((T2-THYST)\). \(THYST\) is an internally set 5°C typical hysteresis.

The LM56 is available in an 8-lead Mini-SO8 surface mount package and an 8-lead small outline package.

Applications
- Microprocessor Thermal Management
- Appliances
- Portable Battery Powered 3.0V or 5V Systems
- Fan Control
- Industrial Process Control
- HVAC Systems
- Remote Temperature Sensing
- Electronic System Protection

Features
- Digital outputs support TTL logic levels
- Internal temperature sensor
- 2 internal comparators with hysteresis
- Internal voltage reference
- Currently available in 8-pin SO plastic package
- Future availability in the 8-pin Mini-SO8 package

Key Specifications
- Power Supply Voltage 2.7V–10V
- Power Supply Current 230 µA (max)
- \(V_{REF}\) 1.250V ±1% (max)
- Hysteresis Temperature 5°C
- Internal Temperature \((+6.20 \text{mV/°C} \times T) +395 \text{mV}\) Sensing Output Voltage
- Temperature Trip Point Accuracy:

Typical Application

$$V_{T1} = 1.250V \times \frac{(R1)}{(R1 + R2 + R3)}$$

$$V_{T2} = 1.250V \times \frac{(R1 + R2)}{(R1 + R2 + R3)}$$

where:

$$R_1 + R_2 + R_3 = 27k\Omega$$

and:

$$V_{T1} \text{ or } T2 = [6.20 \text{ mV/}^\circ\text{C} \times T] + 395 \text{ mV}$$

therefore:

$$R_1 = \frac{V_{T1}}{(1.25V)} \times 27k\Omega$$

$$R_2 = \frac{V_{T2}}{(1.25V)} \times 27k\Omega - R1$$

$$R_3 = 27k\Omega - R1 - R2$$

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may degrade when the device is not operated under the listed test conditions.

**Note 2:** When the input voltage ($V_I$) at any pin exceeds the power supply ($V_I < \text{GND}$ or $V_I > V^+$), the current at that pin should be limited to 5 mA. The 20 mA maximum package input current rating limits the number of pins that can safely exceed the power supplies with an input current of 5 mA to four.

**Note 3:** The maximum power dissipation must be derated at elevated temperatures and is dictated by $T_{J,\text{max}}$ (maximum junction temperature), $\theta_{JA}$ (junction to ambient thermal resistance) and $T_A$ (ambient temperature). The maximum allowable power dissipation at any temperature is $P_D = (T_{J,\text{max}} - T_A)/\theta_{JA}$ or the number given in the Absolute Maximum Ratings, whichever is lower. For this device, $T_{J,\text{max}} = 125^\circ$C. For this device the typical thermal resistance ($\theta_{JA}$) of the different package types when board mounted follow:

<table>
<thead>
<tr>
<th>Package Type</th>

</thead>
<tbody>
<tr>
<td>M08A</td>
<td>110˚C/W</td>
</tr>
<tr>
<td>MUA08A</td>
<td>250˚C/W</td>
</tr>
</tbody>
</table>

**Note 4:** The human body model is a 100 pF capacitor discharge through a 1.5 kΩ resistor into each pin. The machine model is a 200 pF capacitor discharged directly into each pin.

**Note 5:** See AN450 “Surface Mounting Methods and Their Effects on Product Reliability” or the section titled “Surface Mount” found in any post 1986 National Semiconductor Linear Data Book for other methods of soldering surface mount devices.

**Note 6:** Typicals are at $T_J = T_A = 25^\circ$C and represent most likely parametric norm.

**Note 7:** Limits are guaranteed to National’s AOQL (Average Outgoing Quality Level).

1.0 PIN DESCRIPTION

V+ This is the positive supply voltage pin. This pin should be bypassed with 0.1 µF capacitor to ground.

GND This is the ground pin.

VREF This is the 1.250V bandgap voltage reference output pin. In order to maintain trip point accuracy this pin should source a 50 µA load.

VTEMP This is the temperature sensor output pin.

OUT1 This is an open collector digital output. OUT1 is active LOW. It goes LOW when the temperature is greater than T1 and goes HIGH when the temperature drops below T1 – 5°C. This output is not intended to directly drive a fan motor.

OUT2 This is an open collector digital output. OUT2 is active LOW. It goes LOW when the temperature is greater than the T2 set point and goes HIGH when the temperature is less than T2 – 5°C. This output is not intended to directly drive a fan motor.

VT1 This is the input pin for the temperature trip point voltage for OUT1.

VT2 This is the input pin for the low temperature trip point voltage for OUT2.

\[
V_{T1} = \frac{1.250\text{V} \times R_1}{R_1 + R_2 + R_3}
\]

\[
V_{T2} = \frac{1.250\text{V} \times (R_1 + R_2)}{R_1 + R_2 + R_3}
\]

where:

(R1 + R2 + R3) = 27 kΩ

R1 = 6.20 mV/°C x T + 395 mV therefore:

R1 = \frac{V_{T1}/1.25\text{V}}{27 \text{kΩ}}

R2 = \frac{V_{T2}/(1.25\text{V})}{27 \text{kΩ}} - R1

R3 = 27 kΩ - R1 - R2
Application Hints

2.0 LM56 TRIP POINT ACCURACY SPECIFICATION

For simplicity the following is an analysis of the trip point accuracy using the single output configuration shown in Figure 2 with a set point of 82°C.

Trip Point Error Voltage = $V_{TPE}$

Comparator Offset Error for $V_{T1E}$

Temperature Sensor Error = $V_{TSE}$

Reference Output Error = $V_{RE}$

1. $V_{TPE} = \pm V_{T1E} - V_{TSE} + V_{RE}$

Where:

2. $V_{T1E} = \pm 8 \text{ mV (max)}$

3. $V_{TSE} = (6.20 \text{ mV/°C}) \times (\pm 3°C) = \pm 18.6 \text{ mV}$

4. $V_{RE} = 1.250\text{V} \times (\pm 0.01) \frac{R2}{(R1 + R2)}$

Using Equations from page 1 of the datasheet.

$V_{T1} = 1.250\text{V} \times \frac{R2}{(R1 + R2)} = (6.20 \text{ mV/°C})(82°C) + 395 \text{ mV}$

Solving for $\frac{R2}{(R1 + R2)} = 0.7227$

then,

5. $V_{RE} = 1.250\text{V} \times (\pm 0.01) \frac{R2}{(R1 + R2)} = (0.0125) \times (0.7227) = \pm 9.03 \text{ mV}$

The individual errors do not add algebraically because, the odds of all the errors being at their extremes are rare. This is proven by the fact the specification for the trip point accuracy stated in the Electrical Characteristic for the temperature range of −40°C to +125°C, for example, is specified at ±3°C for the LM56BIM. Note this trip point error specification does not include any error introduced by the tolerance of the actual resistors used, nor any error introduced by power supply variation.

If the resistors have a ±0.5% tolerance, an additional error of ±0.4°C will be introduced. This error will increase to ±0.8°C when both external resistors have a ±1% tolerance.

3.0 BIAS CURRENT EFFECT ON TRIP POINT ACCURACY

Bias current for the comparator inputs is 300 nA (max) each, over the specified temperature range and will not introduce considerable error if the sum of the resistor values are kept to about 27 kΩ as shown in the typical application of Figure 1. This bias current of one comparator input will not flow if the temperature is well below the trip point level. As the temperature approaches trip point level the bias current will start to flow into the resistor network. When the temperature sensor output is equal to the trip point level the bias current will be 150 nA (max). Once the temperature is well above the trip point level the bias current will be 300 nA (max). Therefore, the first trip point will be affected by 150 nA of bias current. The leakage current is very small when the comparator input transistor of the different pair is off (see Figure 3).

The effect of the bias current on the first trip point can be defined by the following equations:

$$K_1 = \frac{R1}{R1 + R2 + R3}$$

$$V_{T1} = K_1 \times V_{REF} + K_1 \times (R2 + R3) \times \frac{I_B}{2}$$

where $I_B = 300 \text{nA}$ (the maximum specified error).

The effect of the bias current on the second trip point can be defined by the following equations:

$$K_2 = \frac{R1 + R2}{R1 + R2 + R3}$$

$$V_{T2} = K_2 \times V_{REF} + \left( \frac{K_1 + K_2}{2} \right) \times R3 \times I_B$$

where $I_B = 300 \text{nA}$ (the maximum specified error).

The closer the two trip points are to each other the more significant the error is. Worst case would be when $V_{T1} = V_{T2} = V_{REF}/2$. 
4.0 MOUNTING CONSIDERATIONS

The majority of the temperature that the LM56 is measuring is the temperature of its leads. Therefore, when the LM56 is placed on a printed circuit board, it is not sensing the temperature of the ambient air. It is actually sensing the temperature difference of the air and the lands and printed circuit board that the leads are attached to. The most accurate temperature sensing is obtained when the ambient temperature is equivalent to the LM56's lead temperature.

As with any IC, the LM56 and accompanying wiring and circuits must be kept insulated and dry, to avoid leakage and corrosion. This is especially true if the circuit may operate at cold temperatures where condensation can occur. Printed-circuit coatings and varnishes such as Humiseal and epoxy paints or dips are often used to ensure that moisture cannot corrode the LM56 or its connections.
5.0 $V_{\text{REF}}$ AND $V_{\text{TEMP}}$ CAPACTIVE LOADING

The LM56 $V_{\text{REF}}$ and $V_{\text{TEMP}}$ outputs handle capacitive loading well. Without any special precautions, these outputs can drive any capacitive load as shown in Figure 4.

6.0 NOISY ENVIRONMENTS

Over the specified temperature range the LM56 $V_{\text{TEMP}}$ output has a maximum output impedance of 1500$\Omega$. In an extremely noisy environment it may be necessary to add some filtering to minimize noise pickup. It is recommended that 0.1 $\mu$F be added from $V^+$ to GND to bypass the power supply voltage, as shown in Figure 4. In a noisy environment it may be necessary to add a capacitor from the $V_{\text{TEMP}}$ output to ground. A 1 $\mu$F output capacitor with the 1500$\Omega$ output impedance will form a 106 Hz lowpass filter. Since the thermal time constant of the $V_{\text{TEMP}}$ output is much slower than the 9.4 ms time constant formed by the RC, the overall response time of the $V_{\text{TEMP}}$ output will not be significantly affected. For much larger capacitors this additional time lag will increase the overall response time of the LM56.

7.0 APPLICATIONS CIRCUITS

The circuit shown in Figure 5 will reduce the effective bias current error for $V_{\text{T2}}$ as discussed in Section 3.0 to be equivalent to the error term of $V_{\text{T1}}$. For this circuit the effect of the bias current on the first trip point can be defined by the following equations:

$$K_1 = \frac{R_2}{R_1 + R_2}$$

$$V_{\text{T1}} = K_1 \times V_{\text{REF}} + K_1 \times \left(\frac{R_1}{R_2}\right) I_b$$

where $I_b = 300$ nA (the maximum specified error).

Similarly, bias current affect on $V_{\text{T2}}$ can be defined by:

$$K_2 = \frac{R_4}{R_3 + R_4}$$

$$V_{\text{T1}} = K_2 \times V_{\text{REF}} + K_2 \times \left(\frac{R_3}{R_4}\right) I_b$$

where $I_b = 300$ nA (the maximum specified error).

The current shown in Figure 6 is a simple overtemperature detector for power devices. In this example, an audio power amplifier IC is bolted to a heat sink and an LM56 Celsius temperature sensor is mounted on a PC board that is bolted to the heat sink near the power amplifier. To ensure that the sensing element is at the same temperature as the heat sink, the sensor’s leads are mounted to pads that have feed throughs to the back side of the PC board. Since the LM56 is sensing the temperature of the actual PC board the back side of the PC board also has large ground plane to help conduct the heat to the device. The comparator’s output goes low if the heat sink temperature rises above a threshold set by $R_1$, $R_2$, and the voltage reference. This fault detection output from the comparator now can be used to turn on a cooling fan. The circuit as shown in design to turn the fan on when heat sink temperature exceeds about 80°C, and to turn the fan off when the heat sink temperature falls below approximately 75°C.

LIFE SUPPORT POLICY

NATIONAL’S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.

2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied and National reserves the right at any time without notice to change said circuitry and specifications.
